Here is my lab, run me though what we doing, what language, what is the task, how can i go about it

Ari, that is completely normal.

`git status` checks your **local Git repository**, not GitHub. When `create-next-app` created the project, it automatically ran something equivalent to:

PowerShell

So your computer already has a local Git repository with a branch called `master`, even though it is not connected to GitHub.

Check whether GitHub is linked:

PowerShell

- **No output:** not linked to GitHub yet.
- A GitHub URL appears: it is already linked.

You can still make your first commit locally:

```
git add .
git commit -m "Set up Next.js project with TypeScript and ESLint"
git push
```

When you create the GitHub repository later, connect it with:

```
git branch -M main
git remote add origin https://github.com/YOUR-USERNAME/coms3011a-lab1.git
git push -u origin main
```

When creating the repository on GitHub, leave it **empty**—do not add another README, licence or `.gitignore`, because your local Next.js project already contains files.

The local commits still count towards the lab's commit-history requirement once they are pushed to GitHub.

why is claude.md there?

Worked for 33s >

Ari, that is normal. The latest `create-next-app` now generates `AGENTS.md` **and** `CLAUDE.md` **automatically** to give coding assistants project-specific Next.js instructions. You did not accidentally connect Claude to the repository, and it does not mean Claude has access to your code.  Next.js +1

They are just Markdown instruction files:

- `AGENTS.md` — general instructions for tools such as Codex and other coding agents.

- `CLAUDE.md` — compatibility instructions aimed at Claude-based coding tools.
- Neither file is needed for Next.js to run.
- Neither file affects your application, database or tests.

Since you are using Codex in VS Code, keeping `AGENTS.md` may be useful. You can remove `CLAUDE.md` if you are not using Claude:

```
Remove-Item CLAUDE.md
git add .
git commit -m "Remove unused Claude agent instructions"
git push
```

Or leave both files there; they will not cost you marks. The lab explicitly permits AI use and instead grades whether your submitted transcripts show clear constraints, corrections and decisions traceable to the finished code. lab_one

My recommendation: **keep** `AGENTS.md` , **remove** `CLAUDE.md` . Cleaner repository, less mysterious robot paperwork.

nermind that, did this count as a commit? how do i check commit history

Yes, Ari — the existing “Initial commit from Create Next App” counts as one commit.

Your GitHub screenshot confirms:

1 Commit

The later `git push` did **not** create another commit; it only uploaded the existing local commit to GitHub. Your failed `fit commit` also created nothing, and `git commit` correctly said there were no new changes.

Check commit history in VS Code

PowerShell

You currently have:

```
f28eded Initial commit from Create Next App
```

For a more detailed visual history:

PowerShell

To exit the log screen, press:

q

Check it on GitHub

On the repository page, click “**1 Commit**” near the top-right of the file list. As you continue, that number should increase.

You currently have **1 of the minimum 6 commits** required for the strongest commit-history mark. Each new commit must follow an actual meaningful change; do not create empty filler commits.

what is a prisma schema

Worked for 18s >

Ari, a **Prisma schema** is the blueprint for your database.

It is usually a file named:

```
prisma/schema.prisma
```

In that file, you define:

- Which database you are using, such as SQLite.
- Which tables should exist.
- The columns in each table.
- Each column's data type.
- Default values and restrictions.

- Relationships between tables.

Prisma then uses that blueprint to create database migrations and generate TypeScript code for reading and writing data.  Prisma +1

Your lab's schema

It will probably look roughly like this:

```
generator client {
  provider = "prisma-client"
  output   = "../src/generated/prisma"
}

datasource db {
  provider = "sqlite"
}

enum TaskStatus {
  TODO
  IN_PROGRESS
  COMPLETE
}

model Task {
  id          Int           @id @default(autoincrement())
  title       String
  description String
  dueDate     DateTime
  topic       String
  status      TaskStatus @default(TODO)
  archivedAt  DateTime?
  createdAt   DateTime      @default(now())
  updatedAt   DateTime      @updatedAt
}
```

What it means

prisma

Creates a database table representing tasks.

prisma

Creates a unique numeric ID:

```
1, 2, 3, 4...
```

```
prisma
```

Creates a required text column.

```
prisma
```

Restricts status to:

```
TODO
IN_PROGRESS
COMPLETE
```

New tasks start as `TODO`.

```
prisma
```

The `?` means it may be empty:

- `null` → task is active.
- Contains a date → task is archived.

```
prisma
```

Automatically records when the task was created.

```
prisma
```

Automatically changes whenever the task is edited.

What should not be in the schema

Do not add:

prisma

Overdue should be calculated from:

```
due date has passed
AND
status is not COMPLETE
```

The schema describes the database's **structure**, not the actual task information. Your SQLite file contains the actual records.

Turning the schema into a database

After writing the schema, Prisma reads it when you run:

PowerShell

```
npx prisma migrate dev --name create-task-table
```

That command creates a migration and updates the SQLite database to match the schema. Prisma models correspond to database tables and also become the basis for the generated TypeScript database client.  Prisma +1

In plain English:

```
schema.prisma = database plan
migration      = instructions for applying the plan
SQLite file    = actual stored task data
Prisma Client  = TypeScript tool used to access that data
```
